# Simplicial complexes

#### Definition

A simplicial complex  $\Delta$  on vertex set V is a collection of subsets  $\tau \subseteq V$ , called faces, that is closed under inclusion.

For a simplicial complex  $\Delta$ , define:

- dim  $\tau := |\tau| 1$  for  $\tau \in \Delta$ ,;
- $each dim \Delta := \max \{ \dim \tau : \tau \in \Delta \};$
- a facet  $\tau$  is a maximal face under inclusion;
- the star of a face  $\tau$  is  $\operatorname{st}_{\Delta} \tau := \{ \sigma \in \Delta : \sigma \cup \tau \in \Delta \};$
- the link of a face  $\tau$  is  $lk_{\Delta} \tau := \{ \sigma \tau \in \Delta : \tau \subseteq \sigma \in \Delta \};$
- a missing face τ is a subset of V(Δ) such that τ is not a face of Δ but every proper subset of τ is.

 $\Delta$  is called *pure*, if all of its facets have the same dimension.

 $\Delta$  is called *prime*, if it is pure and has no missing facets.

200

### Face-number related invariants

Let  $\Delta$  be a (d-1)-dimensional simplicial complex.

### Definition

The *f*-number  $f_i = f_i(\Delta)$  denotes the number of *i*-dimensional faces of  $\Delta$ . The vector  $(f_{-1}, f_0, \dots, f_{d-1})$  is called the *f*-vector.

### Definition

The *h*-vector of  $\Delta$ ,  $(h_0, h_1, \cdots, h_d)$ , is defined by the relation  $\sum_{j=0}^{d} f_{j-1}(x-1)^{d-j} = \sum_{i=0}^{d} h_i x^{d-i}$ .

### Definition

The g-vector of  $\Delta$  is  $(g_0, g_1, \dots, g_{\lfloor \frac{d}{2} \rfloor})$  whose entries are given by

• 
$$g_0 = 1;$$

$$g_i = h_i - h_{i-1} \text{ for } 1 \le i \le \left\lfloor \frac{d}{2} \right\rfloor$$

For any simplicial complex  $\Delta$ , there is an associated topological space  $||\Delta||$ .

- A polytope is the convex hull of a finite set of points in some ℝ<sup>e</sup>. It is called a *simplicial d*-polytope if it is *d*-dimensional and all of its facets are simplicial. The boundary complex of a simplicial polytope is called a *polytopal sphere*.
- A simplicial sphere (resp. manifold) is a simplicial complex whose geometric realization is homeomorphic to a sphere (resp. manifold).

**Central question**: Characterize simplicial manifolds with small  $g_i$ ,  $i \ge 2$ .

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ろのぐ

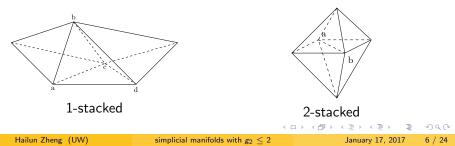

# (r-1)-stacked spheres

Given a simplicial ball  $\Delta$ , the faces of  $\Delta - \partial \Delta$  are called the *interior* faces of  $\Delta$ .

#### Definition

Let  $\Delta$  be a simplicial *d*-ball.  $\Delta$  is said to be (r-1)-stacked if  $\Delta$  has no interior *k*-faces for  $k \leq d-r$ . An (r-1)-stacked simplicial sphere is the boundary complex of an (r-1)-stacked triangulation of a simplicial ball.

**Remark**: 1-stacked = stacked.

# Previous results, $g_2 = 0$

### Theorem (Kalai, 1987)

Let  $\Delta$  be a simplicial manifold of dimension  $d \ge 2$ . Then  $g_2 \ge 0$ . Furthermore, if  $d \ge 3$ , then equality holds if and only if  $\Delta$  is a stacked sphere.

#### **Remarks:**

- The theorem continues to hold in the class of normal pseudomanifolds.
- The proof is based on rigidity theory of graphs.

IN INCO

## Previous results, $g_i = 0$ for $i \ge 2$

### Theorem (Murai-Nevo, 2013)

Let  $\Delta$  be polytopal (d-1)-sphere and  $2 \le r \le d/2$ . Then  $g_r(\Delta) = 0$  if and only if  $\Delta$  is (r-1)-stacked.

### **Remarks:**

- The theorem is also true for homology spheres with weak Lefschetz property over a field of characteristic 0.
- The proof is based on commutative algebra tools.

イロト 不得 トイヨト イヨト ヨー シタウ

### Previous result 3, $g_2 = 1$

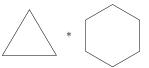

Given two simplicial complexes  $\Delta_1$  and  $\Delta_2$  on disjoint vertex sets, define their join,  $\Delta_1 * \Delta_2$ , as the complex on vertex set  $V(\Delta_1) \cup V(\Delta_2)$  whose faces are  $\{\tau_1 \cup \tau_2 : \tau_1 \in \Delta_1, \tau_2 \in \Delta_2\}$ . We also denote the boundary complex of the *i*-dimensional simplex as  $\partial \sigma^i$ .

### Theorem (Nevo-Novinsky, 2011)

Let  $d \ge 4$ , and let  $\Delta$  be a prime simplicial (d - 1)-sphere and  $g_2(\Delta) = 1$ . Then  $\Delta$  is combinatorially isomorphic to one of the following cases:

• 
$$\partial \sigma^i * \partial \sigma^{d-i}$$
, where  $2 \leq i \leq d-2$ ;

2  $\partial \sigma^{d-2} * C$ , where C is a cycle.

イロト 不得 トイヨト イヨト ヨー シタウ

# Central retriangulation, definition

### Definition

Assume that

- Δ is a *d*-dimensional simplicial complex;
- B is a subcomplex of  $\Delta$  which is also a simplicial d-ball.

The **central retriangulation** of  $\Delta$  along *B*, denoted as  $\operatorname{crtr}_B(\Delta)$ , is the new complex we obtain after

- removing all of the interior faces of B;
- **2** replacing them with the interior faces of the cone on  $\partial B$ .

(the cone point is a new vertex v.)

# Central retriangulation, examples

### **Examples:**

 $f(\Delta) = f(\operatorname{crtr}_B(\Delta)) = (1, 11, 20, 10)$ 

 $g_2(\operatorname{crtr}_B(\Delta)) = g_2(\Delta) + (\# \text{ of new edges} - 4 \cdot (\# \text{ of new vertices}) = 1).$ 

Sac

# Central retriangulation, properties

Any (r-1)-stacked sphere S uniquely determines an (r-1)-stacked ball whose boundary complex is S. We denotes this (r-1)-stacked ball by S(r-1).

### **Properties:**

- If the retriangulated subcomplex B is an (r-1)-stacked ball, where  $2 \le r \le d/2$ , then  $g_i(\operatorname{crtr}_B(\Delta)) = g_i(\Delta) + g_{i-1}(\partial B)$  for  $1 \le i \le d/2$ .
- If B is the union of some facets of ∆ whose facet-ridge graph is a tree, then B is a stacked ball.

### Inverse stellar retriangulation, definition

#### Definition

Let  $\Delta$  be a *d*-dimensional simplicial complex. Assume that there is a vertex  $v \in V(\Delta)$  such that

1  $lk_{\Delta} v$  is a (r-1)-stacked (d-1)-sphere for some  $2 \le r \le d/2$ ;

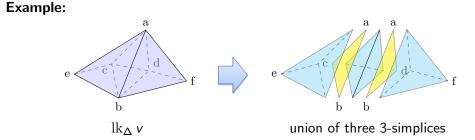

**2** no interior face of  $(lk_{\Delta} v)(r-1)$  is a face of  $\Delta$ .

Then define the *inverse stellar retriangulation* on vertex v by

$$\operatorname{sd}_{\nu}^{-1}(\Delta) = (\Delta \setminus \{\nu\}) \cup (\operatorname{lk}_{\Delta} \nu)(r-1).$$

イロト 不得 トイヨト イヨト ヨー シタウ

## Inverse stellar retriangulation, properties

Properties of inverse stellar retriangulation:

# The Swartz operation, part 1

### Definition

Let  $\Delta$  be a simplicial (d-1)-manifold. If a missing facet  $\tau$  of  $lk_{\Delta} v$  is also a missing face of  $\Delta$ , then we define the *Swartz operation* on  $(v, \tau)$  of  $\Delta$  by

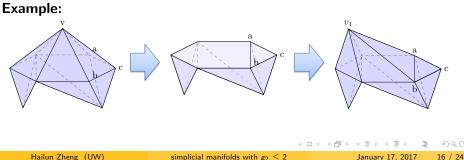

- 1 removing v;
- 2 adding  $\tau$  to  $\Delta$ ;
- Coning off two remaining simplicial spheres S<sub>1</sub>, S<sub>2</sub> with two new vertices v<sub>1</sub>, v<sub>2</sub>.

(Here  $S_1$ ,  $S_2$  are the two simplicial spheres such that their connected sum by identifying the face  $\tau$  is  $lk_{\Delta} v$ .)

イロト 不得 トイヨト イヨト ヨー シタウ

## The Swartz operation, part 2

- If any of the two spheres, say  $S_1$ , is the boundary complex of a simplex, then we add the simplex to  $\Delta \cup \{\tau\}$  instead of coning off  $S_1$ with  $v_1$ . The resulting complex is denoted by  $so_{v,\tau}(\Delta)$ .
- 2 If dim  $\Delta \geq 3$ , then iterating this process, we add all missing facets of  $lk_{\Delta} v$  to  $\Delta$ . The resulting complex is denoted by  $so_{v}(\Delta)$ .

# The Swartz Operation, properties

Properties of the Swartz Operation:

- $so_{\nu}^{-1}(\Delta)$  is PL-homeomorphic to  $\Delta$ .
- **2** If  $lk_{\Delta} v$  is stacked, then  $so_{v}(\Delta) = sd_{v}^{-1}(\Delta)$ .
- **③** If  $\Delta$  is of dimension  $\geq$  3, then

$$g_2(so_v(\Delta)) = g_2(\Delta) - \#\{\text{missing facets of } lk_\Delta v\}.$$

Simplification: It suffices to consider prime simplicial manifolds.

### Theorem (Zheng, 2016)

Let  $d \ge 5$ , and let  $\Delta$  be a prime simplicial (d - 1)-manifold with  $g_2(\Delta) = 1$ . Then  $\Delta$  is obtained by centrally retriangulating a stacked (d - 1)-sphere along the star of one of its faces, whose dimension, *i*, satisfies 0 < i < d - 1.

#### Corollary

This  $\Delta$  is either the join of  $\partial \sigma^i$  and  $\partial \sigma^{d-i}$ , where  $2 \leq i \leq d-2$ , or the join of  $\partial \sigma^{d-2}$  and a cycle.

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ろのぐ

### Sketch of Proof, part 1

The starting point:

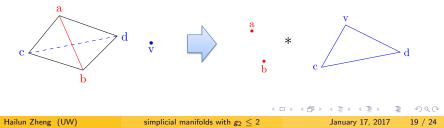

L

$$\sum_{v \in V(\Delta)} g_2(\operatorname{lk}_\Delta v) = d - 1 + 3g_3(\Delta) = d + 2 ext{ or } d - 1.$$

**Case 1**: Every vertex link has  $g_2 = 1$ .

 $\Rightarrow \Delta$  is the join of two boundary complexes of simplices.

 $\Rightarrow$  It is obtained by centrally retriangulating  $\partial\sigma^d$  along the star of a face.

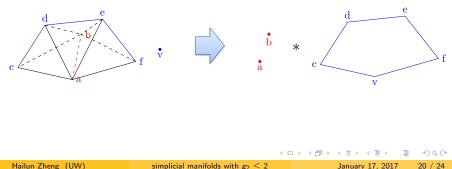

### Sketch of proof, part 2

**Case 2**: There is a vertex link with  $g_2 = 0$ .

 $\Rightarrow \Delta$  is the join of a cycle and  $\partial \sigma^{d-2}$ .

 $\Rightarrow$  It is obtained by centrally retriangulating a certain stacked sphere along the union of two facets.

### Theorem (Zheng, 2016)

Let  $d \ge 4$ . Every prime simplicial (d - 1)-manifold with  $g_2 = 2$  is either the octahedral 3-sphere (in this case d = 4), or it can be obtained from a polytopal (d - 1)-sphere with  $g_2 = 0$  or 1, by centrally retriangulating along some stacked subcomplex.

#### Corollary

All simplicial (d-1)-spheres with  $g_2 \leq 2$  are polytopal.

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 ろのぐ

# Additional remarks

- Both of the main theorems continue to hold for the class of normal pseudomanifolds when the dimension d 1 is at least 4.
- For all d ≥ 4, there are triangulations of ℝP<sup>2</sup> \* S<sup>d-4</sup> that have g<sub>2</sub> = 3. This implies that our theorem cannot be extended to higher g<sub>2</sub> in the class of normal pseudomanifolds.
- It appears that many non-polytopal spheres that are known so far have g<sub>2</sub> ≥ 5: the Barnette sphere: g<sub>2</sub> = 5; all non-polytopal 3-spheres with nine vertices: g<sub>2</sub> ≥ 5.
